NAME: Jagriti Mohan

SRN: PES2UG24CS200

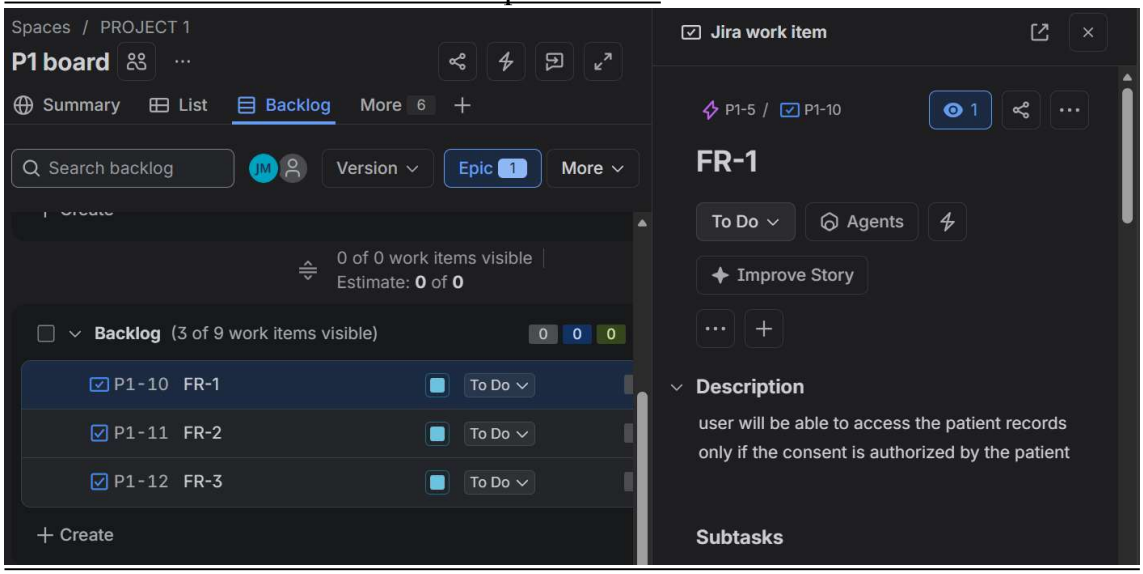

SECTION: 5TH CSE "D"

Lab-2: Setting up Jira for the given Problem statement and requisites

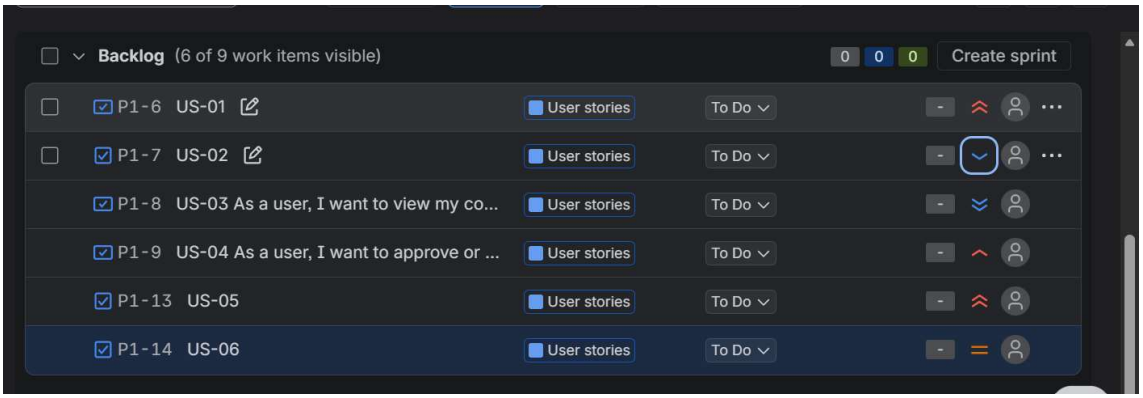

- Constructed Epics

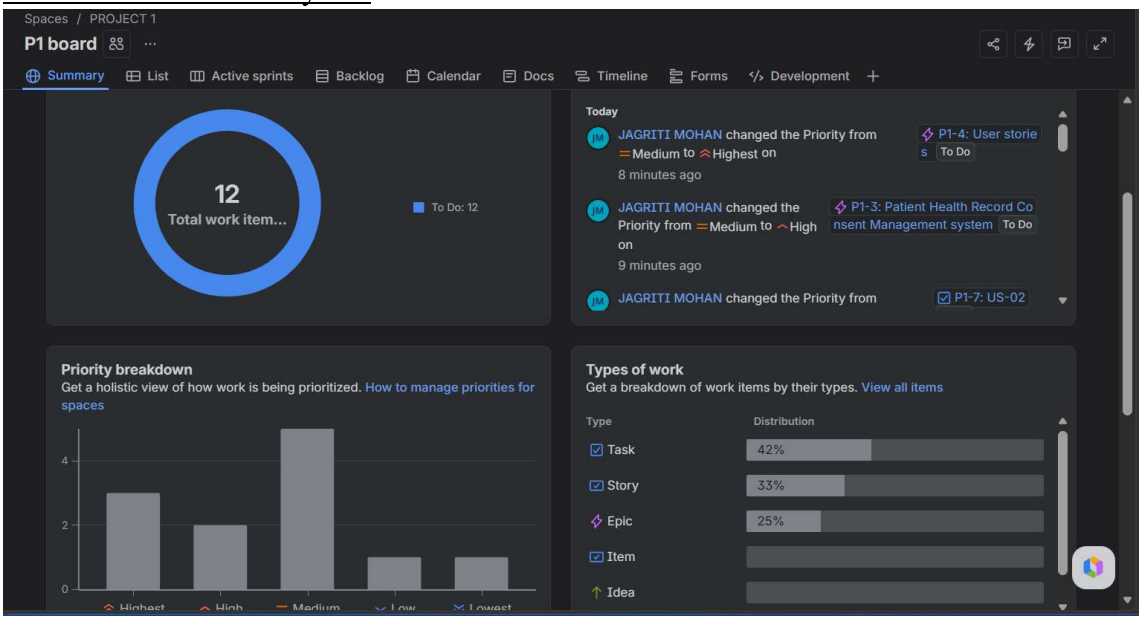

- Functional and Non-Functional Requirements:

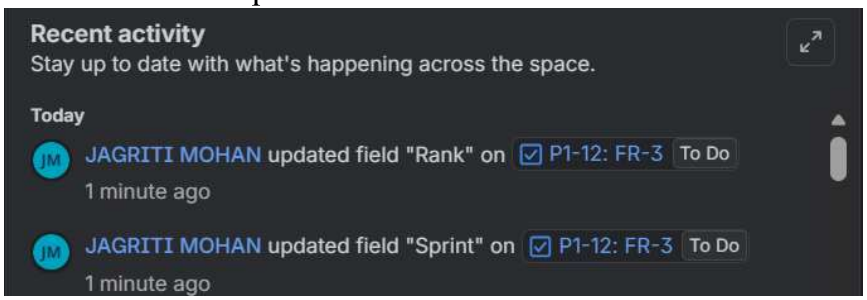

- user stories prioritized via their priority status

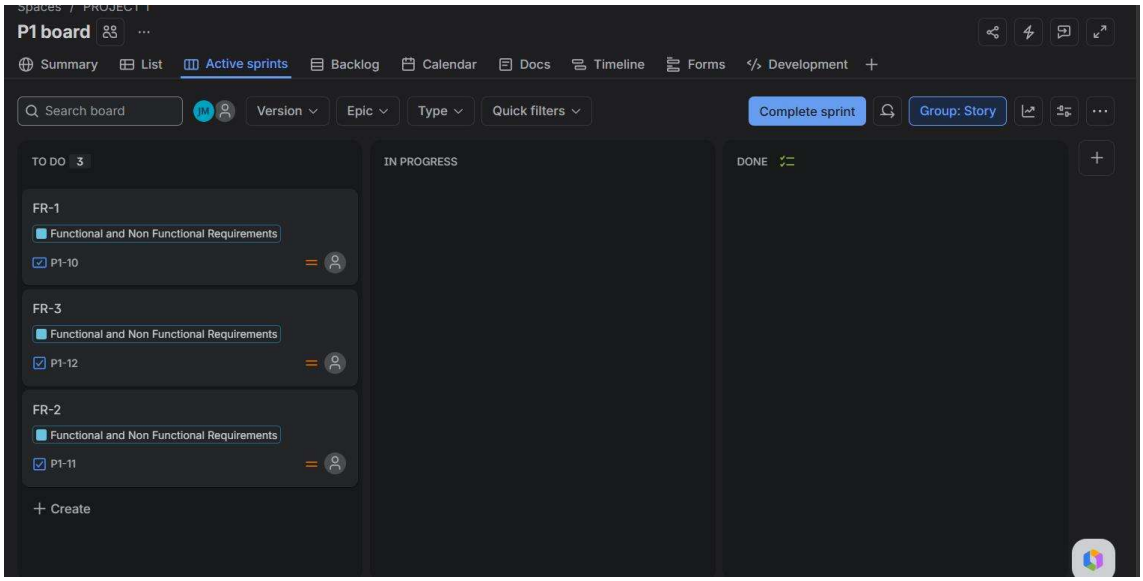

- Status of the summary tab

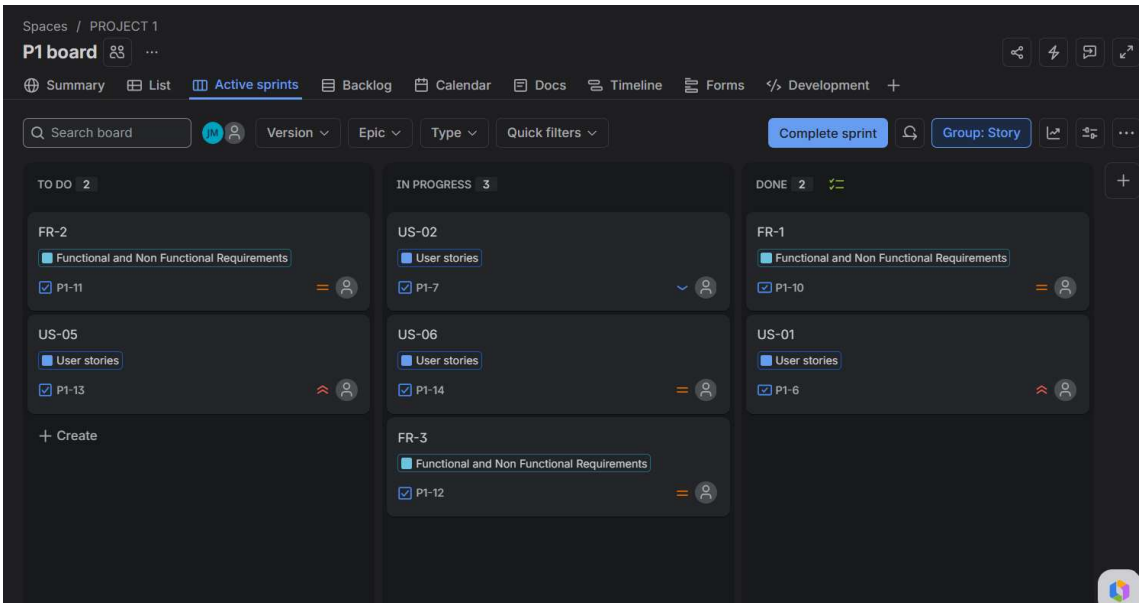

- Creation of first sprint in the scrum field

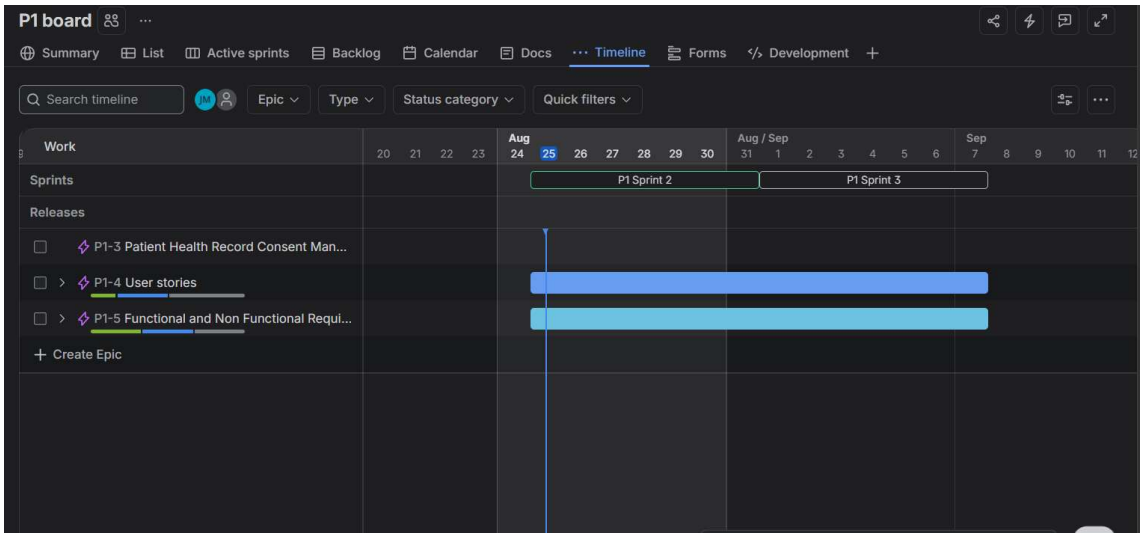

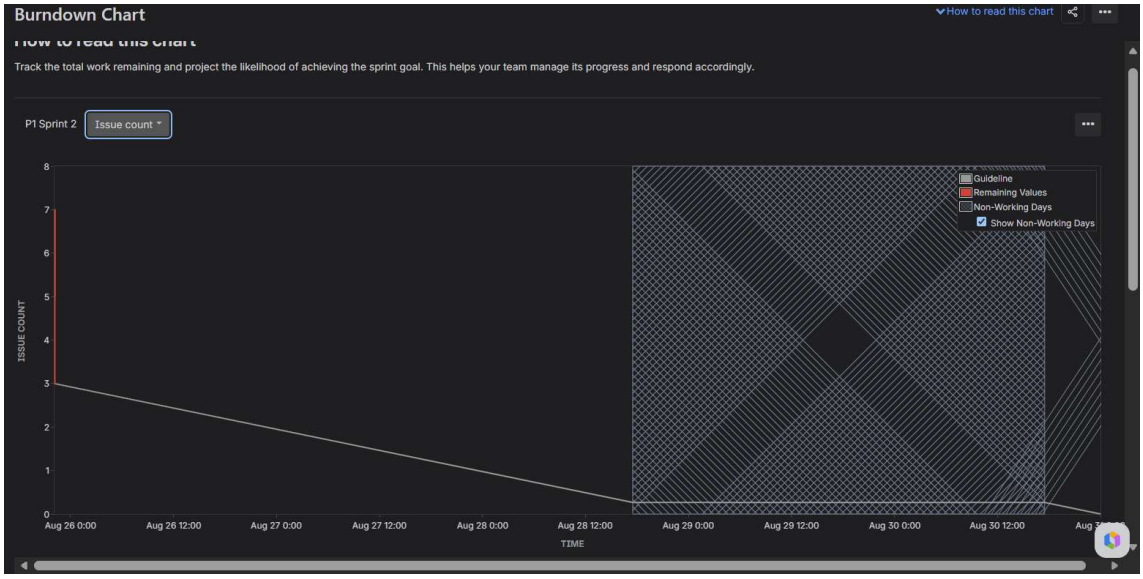

- Featuring sprint after editing the “in-progress” and “Done” fields

- Timeline

- Burndown chart

1. Did your estimations reflect the actual effort?
Partially. The estimates gave the team a useful starting point, but the simulated chart shows that progress was slower than the ideal pace during the first few days. This suggests that some tasks may have involved integration, testing, or clarification effort that was not fully visible during estimation. In the next sprint, the team should break large stories into smaller tasks and use past sprint data to estimate more accurately.

2. Was your backlog well-prioritized?
Mostly yes. Authentication, consent creation, and validation were prioritized first because they are essential to the system's secure core workflow. Dashboard display, audit logging, and notifications follow to complete the experience and improve traceability. The order should still be reviewed with the product owner and adjusted for dependencies, risks, and user value.

3. How did your simulated sprint align with your plan?
The sprint finished all 30 story points by Day 5, so the planned scope was completed. However, the simulated actual burndown was behind the ideal line through Day 4. This indicates that finishing the work required a stronger pace toward the end. A real team should investigate the cause rather than assume the same pattern: examples include blocked tasks, underestimated complexity, or testing taking longer than expected.

4. What insights did the burndown chart give about your team's capacity?
The chart suggests that the team could complete the planned 30 story points within this simulated five-day sprint, but progress was uneven. Capacity should not be judged from one simulation alone. Across several real sprints, completed story points, team availability, unfinished work, and blockers can help establish a more reliable forecast. The team should avoid increasing scope simply because it finished on the final day.
